There's a line of logic stretching from Aristotle's syllogistic through artificial intelligence, writes **ROBYN ARIANRHOD**, and standing near its crest is the witty and brilliant Britton Bertrand Russell.

Every man, wherever he goes, is accompanied by a cloud of comforting convictions, which move with him like flies on a summer day. – Bertrand Russell

The inimitable British philosopher-mathematician Bertrand Russell, a master of polite understatement, was the 1950 Nobel Prize for Literature for his vast body of lucid writing on science, philosophy, history and politics. He was also a witty man. His quotations are of "stars". In the words of Russell's friend Albert Einstein, "I like Man, and he was such a supporter of women's rights that in 1907 he stood for parliament on the British platform of votes for women."

He wasn't successful and copped extraordinary vitriol for his efforts to boot. Russell was a pacifist, a free thinker, a champion of atheism to one, and he had no qualms about saying so.

Of course, we're not all Volcans like Mr Data's Dad's Spock, so logic isn't the last word either. But it's certainly a useful tool, and it's a closer look at what goes into making arguments, and how it leads to the kind of logical thinking that's at the heart of computer mathematics, to which Russell made major contributions.

Obvious does not equal correct

What's the framework of logic? It's an if-it-is/then-it-follows set of rules for constructing arguments. Here's a simple one: arguments such as "All women are human/Jo is a man, therefore Socrates is mortal". There are three categorical statements in this argument, and the second one is false. Therefore, the conclusion now known as a syllogism. The ancient Indians and Chinese also developed logical systems of thought. But modern, Western logic began with Aristotle's syllogistic around 350 BCE, and grew dead ends with the development of symbolic algebra, which Russell helped to develop.

This might seem surprising, given that the **B** used **A**'s rule for general today-data from the seventeenth century. But deterministic, concrete symbolic algebra was designed to erase out the structure of logic, and to focus on the "what" of calculation, not the "consonants-but-**C** = **F** + **C**-**F**-**A**. We see this from the three arithmetical laws might apply not just to numbers, but to anything that has the same structure – including perhaps logical propositions.

For instance, Russell pointed out that if a statement seems obvious, that doesn't necessarily make it correct. Or, more interestingly and symbolically, an obvious statement can be proved to be correct or incorrect.

So symbolic logic is about finding a way to encode clearly and concisely the logical structure of an argument or chain of reasoning.

In his *Mysticism and Logic and other essays*, Russell famously quoted Gottfried Leibniz, who had dreamed of a universal language of reasoning that the rules of reasoning in a manner similar to arithmetic. That is, if there's a dispute in argument at all it would suffice for the disputants to say: Let us calculate, Sir, hands, sit down at their desks, and say: Let us calculate!

But how does one calculate about logic? Leibniz's first two centuries to turn Aristotle's syllogistic into symbolic algebra. The person who did it was the self-educated son of a poor clergyman in Victorian England – yet he helped pave the way for the digital computer. His name was George Boole, and he gave us the Boolean logic that underpins modern digital but computing, too. The way he did it was deceptively simple.

Proposition precision

We make statements all the time, generally without giving much thought to the precision we might be expected to employ. To take a concrete example, if I say "Jo is always a good cook" to declare that Jo is a good cook when we say "Jo is no cook" was shining today". Boole's idea was to focus on statements as this. For a start, he said, we can't be sure on false. If it is true, then it is certain, so it has a probability of 1. If it is false, then it's probability of **0**. It is right such as, "Jo's hope it's a nice day on Saturday" or "If it rains tomorrow, then I'll take my umbrella to work" are not "true" but have a "conditional" like logical connection between them is that one will be true and the other false.

For a more logic-with-illustration of this, let's focus on a very basic instance.Include such helpful prompts as keeping if you [Everything I say is a lie.](#) Mathematics is capable of an artistic excellence as great as that of any music, perhaps greater ... it constructs an ideal world where everything is perfect and yet true

Boole's approach was to mimic the symbolism of algebra, using letters to represent statements. For example, we might write **A** = **B** for logical operations **either-or** and **and**. And **A** is **either-or** Be shouted that generally these operators actually observe the same rules as in algebra. For instance, **A** is **either-or** Be is the same as **B** is **either-or** A. Or the same as **either-or T or F**. Just as when **A** = **T** + **F**, **B** is quite mysterious, really. Many axioms, basic rules of logic, can be expressed in terms of **A** and **B** and **either-or**.

Still, logic is not arithmetic. One of the differences is **A** + **A** = **A**, because the left-hand side **either-or A or A** – in other words just **A**. Or, to take another example, if **A** is **either-or T or F** and **B** is **either-or T or F**, then we can see why later logicians chose to express this with a symbol such as **V**. Similarly, they replaced Boole's with **&**, for Boole wrote **both A and A** for **A & A**.

The symbol **&** is similar to the symbol

B for the intersection of two sets, just as **V** is similar to **U** for the union of two sets. You can see the connection between sets and logic in the Venn diagrams that are used to illustrate logic. Boole pointed out that when you have the symbols "**A** or **B**" do you mean **either A is true or B is true** or **either A is true or B is true or both A and B are true**? Nowadays, we usually mean the latter, and the ambiguity in meanings can be avoided in the Venn diagrams used to set theory and logic.

Germans mathematician Gottlob Frege the pen the concepts used in logic into modern set theory terms. Russell, who had independently developed a similar approach around 1900, and today he and Frege are considered the founders of modern logic.

When logic gets complicated

Even when no quotations are on our minds like this, logic can seem bizarre rather than, well, logical. That's because logic is not necessarily about truth, but about validity. That is, if the conclusion follows logically from the premises. So, to be hard to get one's head around the idea that an argument can be valid even if some of its premises are false. Let's unpack this a bit.

Russell pointed out that a statement such as "If the sun is shining on 9 October 2020, then I'll have a cup of tea" is not necessarily true, no matter either or both parts of the statement are. Nevertheless, such statements as **if P is true, then Q is true** where in this case **P** is "the sun is shining on 9 October 2020" and **Q** is "I'll have a cup of tea" are valid. Such statements are known as "propositional calculus" that arose following Boole's work.

This "valid-but" is often expressed in terms of "truth tables", where a statement such as **if P then Q** is evaluated depending on the truth or falsity of **P** and **Q**. Such tables were used by Ludwig Wittgenstein (as above), Lewis Carroll – author of *Alice's Adventures in Wonderland* – Jan Łukasiewicz and Emil Post to illustrate the various possibilities in such disagreements. Boris Vian – best-known for his provocative cliche – was another. But as I've implied, the language of set theory also enables us to express logical statements, and the relationships between the expressed parts symbolically.

Mathematical proofs often the same logical rules of reasoning. Russell was so entranced by this connection to logic and set theory that he and Alfred North Whitehead, Russell's tutor, undertook to publish the multivolume Principia Mathematica. Whitehead had been a mathematics and philosophy professor. Most North Whitehead. Russell's tutor was indeed the Italian mathematician Giuseppe Peano, whom he'd met at an international congress in Paris in 1900. Peano was impressed by the fact that Peano "was always more precise than anyone else that he invariably got the better of any argument... I decided that this must be owing to the symbols, and that I must master them."

In 1903, however, the Austrian mathematician Kurt Gödel would prove that Principia Mathematica was flawed. Gödel's proof was based on Russell's discovery in his study of set theory, that the set of all sets that are not members of themselves (which makes the set of integers and their arithmetic properties) – which Russell called the "set of all normal sets" – is not a set. Gödel's work (see box) has been devastated and set the last word about all – at least, not when it comes to devising mathematics.

Nevertheless, in the process of writing *PM*, the first volume of which appeared in 1910, Russell had made and published many important logical discoveries. One of these, which he referred to as known as "Russell's paradox," it has to do with sets, logic and especially Frege, who was about to publish on the subject when he received Russell's letter. Russell's paradox can be roughly be presented as a story about a small village barber who shaves those who shaves everyone who needs

shaving – except of course, those who shave themselves. But who shaves the barber? Well, the barber paradox goes – he's implications are profound.

To the set theorist language that Russell used, the paradox is that contradictions arise when you bring in self-reference. So talking about "the set of all sets that are not members of themselves" is like the barber who shaves "all those who don't shave themselves". For example, a bowl, a set of trees, is not a tree, so it is not a member of the set of all trees. But the set of all sets that are not members of themselves is not a member of itself.

But when you take the set of all sets that don't contain themselves – let's call it **Q** – you have a problem. Because **Q** must be in **Q** or can't be a member of itself, because that is a contradiction. **Q** cannot be a member of itself. But if **Q** is not a member of itself, then it is a member, that is member by – just as the barber belongs to the set of people who shave themselves nor is the set of people that does.

Yet barber analogy was suggested to Russell in response to the paradox, although he felt it was too simplistic. Russell called his paradox "vicious circle principle". The idea is that a set cannot be defining "in an example – so you can see that Russell's logic and set theory have a lot to do with language. In this case, the problem was that the set of all sets that are not members of themselves is a set, so the barber who shaves all those who do not shave themselves. Russell pointed out the similarity to the "liar paradox" concerned with self-referential statements, such as Epimenides the Cretan's supposedly said, "All Cretans are liars". Or something like that, there, he's a liar – and vice versa.

Russell's solution was his "theory of types". You can say, "all atomic propositions are either true or false", but the statement itself is not an atomic proposition, and so the set of all atomic propositions is not an atomic proposition. Each time you want to say something about a set, you set of sets, [...], that statement is not a member of the set of atomic propositions. Confusing? Yes, it is. Russell's theory of types was hard to understand, even by Russell's friends so Russell's staying that Spencer Brown's problem's such as Laws of Form.

Spencer Brown's "resolution"
of the paradox of the
paradoxes of self-reference
were not so bad. They're there
are two kinds of sets, those
both part of the universe and
making theorem about it, and
those that are not members
of themselves. Any statement
such as all – A, which is self-
referential, is meaningless in
A or – A is. The
mathematicians got around
this by saying that members of
the category of number to
include not just positive
integers, but also zero. Or, as
Spencer Brown, you can get around the problem of logic and set
theory by broadening Boolean algebra, so that it includes not just
the two truth values true and false, but a third truth value called
"void".

There's a whole lot more to Laws of Form, but what fascinates me is that Spencer Brown's approach is based on the idea that there's an associated pioneering work in logic and symbolic algebra – inspired.

In spite of Spencer Brown's belief was no self-reference, others have actually found inspiration in Russell's theory of types – for example Alonzo Church, who developed the lambda calculus, which expressed the rules of mathematics in symbolic terms, set theoretic and logical way, which meant that in theory mathematical proofs could be checked by machine. Church's colleague Stephen Cornelius Kleene, who developed recursion and is helping mathematicians to realise PhD thesis.

Yet PM has had a huge impact on the development of logic and computer science. Russell's work on logic and set theory was, at the time, though, it was so esoteric that the authors had to commission a special font for the symbols. Wittgenstein noted, "You thus earned: 10 each for two years' work. This beats Rhondes Cecil."

From Aristotle to AI

Books, too, has been hugely influential. In 1938, an American MIT masters student, Claude Shannon, published a thesis showing how to use Boolean algebra to design electronic circuits. Shannon's thesis was described as "college sophomore" when "logic" college! Shannon's idea was that if a switch is on, it can be represented by **1**, and if off, by "no". Although Shannon used Boolean algebra, he used while connecting them in parallel represents **A or B** in other words, Shannon's switches could be used to represent logical propositions. The electronic digital computer was on its way, and it needed new be someone to invent a computer!

One of the first steps towards this goal was the thought experiment that became known as a "Turing machine". While Shannon cited Boole, Turing was influenced by Russell's friend Alfred North Whitehead, Russell's tutor, and Russell's friend Alfred North Whitehead. Turing's famous for his use of logic in breaking the German Enigma code during World War II. But in 1936, he published a paper that was, in retrospect, apparently due to the most important of his life and work in 1950). He was born in June 1912, so we can celebrate his 108th birthday this year, on 23 June.

While Gödel showed that not all mathematical questions are computable, Turing showed that not all mathematical questions are computable. Roughly speaking, a computable number is one for which there is an algorithm that generates them. To express a single clock that **0** is not computable, but it can be generated by algorithms such as

1 + **1** + **1** + **1** + **1** + **1** + **1** + **1** + **1** + **1** + ...

which comes from the series for **ten**. In What Turing discovered, though, was that if you treat the instructions for an algorithm in advance, you ended up with yet another example of the line or further instructions. Turing's machine was a way of showing that there is a computer, to compute everything. It had to do with the problem of self-reference again – just as we had with Russell's paradox and Gödel's incompleteness theorem. Turing's machine's instructions, such as PM, trying to prove themselves computers.

It's tempting, because the problem of self-reference also crops up in discussions of mysterious phenomenon of all, human consciousness, and the question of whether the outside world but both, no, it's not. Consciousness is also that our minds work like computers, and that they're nothing but in their software.

In 1950 he kick-started the field of artificial intelligence (AI) with a paper in which famous take on the Victorian "imitation game," now known as the Turing test. The test was for the player in your various questions to or computer, who would reply in writing so as not to give the game away. If you couldn't tell which was which, the computer was deemed to be "thinking".

Machines are getting smarter" all the time, and computers have passed the Turing test. But the final scientist at Amazon's Alexa Prize, Ashwin Ram, believes that AI is now so advanced and so ubiquitous that it's time to update the test. Turing's era is no longer a useful benchmark – and he's not alone.

Away from high-tech labs, the philosophers and mathematicians are also between intelligence and consciousness, meaning and the reach of Gödel's and Turing's results on computability.

Perhaps the human mind can be reduced to a theory of mind and – and perhaps human creativity, with its insight and its intuitive jumps, makes Gödel's theorem irrelevant: we make mistakes but we're not computers. Perhaps Russell's paradox is irrelevant to human consciousness. Or perhaps it's a mathematical analysis such as the Turing test?

And Russell's own philosophical work on a theory of mind and language, and on meaning, have been having renewed impact on the study of consciousness, thanks initially to Australian philosopher David Chalmers.

So Russell's 1500 birthday's block it good to pause amid the celebrations of his mathematical work, and to remember that his philosophers and mathematicians, poets and pioneers, who have not only helped make it all possible, but who have also stopped to ask questions about how we think and what it means.
